Project Name: JobShop
Group Names: Olivia Mates, Risha Vankalapati, Mansi Madhani

Contributions:

Olivia Mates (30%)

- Added our logo as the app icon for when the user sees the app on their homescreen
- Added a feature to request permissions for both notifications and location services
- Implemented switches for after how many days the user wants notifications about applying to a matched job.
- Implemented local notifications for applying to job reminders
- Implemented a pop-up to add to the user's calendar once they save a job as a reminder to apply
- Set up a "forgot password" button that uses the Firebase reset password function
- On the loading of the app, capture the current location (as city and state) in a global variable if the user has permissions on
- Add a table cell called "Current Location" that allows the user to add their current location to their working locations/current location to make job searching easier and more efficient

Risha Vankalapati (35%)

- Integrated Jobicy API (only free one that serves purpose of the project) for showing the matches to the user, active job posting pulled directly from the API and then converted into a Job Card that appears for the user on MatchesVC
- Implemented a match score based on how many of the skills the user has compared the job postings requirements
- Created scanning for the job description to find skills using the skills csv and also created mappings for lowercase vs uppercase, lingo, etc.. to make sure all skills were displayed on the job card and could be compared to for the match score
- Sorted matches on MatchesVC based on match score to show highest to lowest to user
- Added caching for fetched jobs to prevent maxing out API requests

Mansi Madhani (35%)

- Created pages for users to search for and select their current location, preferred working locations, industry types, job types, and skills. Their selections are also saved to Firestore.
- Updated settings page to show previews of user's selections for each of the above categories.
- Implemented parsing text content from a resume, both by uploading a resume file (PDF or docx) or using the phone's camera.
- Implemented using AI to extract skills from the parsed resume content, after which the user can choose which of these skills they'd like to add to their profile.

Deviations:

- Match score is implemented and the matches are displayed in order of highest match score to lowest, but there is no cutoff for what is shown and not shown to the user so no active recommendations based on skills.
- API is fully integrated and shows jobs, but all postings are currently remote because of chosen API - will integrate another that has non-remote postings.
